The growth rates of infant Japanese monkeys (*Macaca fuscata*) were measured by weight, length, and crown-rump length (CRL). The animals were treated with either oxytocin (OXT) or saline by continuous infusion for a period of 7 weeks. There was a high correlation between the plasma OXT levels and the CRL values. The growth rates were significantly higher in the animals that received continuous OXT infusion than in those that received saline infusion. No significant differences were found in the growth rates between male and female animals. Endoscopically assisted two-stage repair of adult congenital diaphragmatic hernia. Adult congenital diaphragmatic hernia (ACDH) is a rare disease. We have developed a new technique of endoscopically assisted two-stage repair of ACDH. The left diaphragm and liver were exposed by a surgical approach through the right chest. Endoscopy was used to identify the diaphragmatic defect and patent hepatic ducts, and to mobilize the left colon. The left diaphragm and colon were pushed up into the abdominal cavity. A midline laparotomy incision was made through the abdominal wall. The diaphragm was closed in two layers, and a bidirectional end-to-end anastomosis was performed. The first child who underwent the procedure died on postoperative day 6 because of multiple organ failure. The second child successfully underwent the procedure. The procedure seems to be safe for the patient, but it is difficult to be applied widely because of its technical complexity. My best friend and I always have a bit of fun. 82157476af
